So $P(N = k) = 0$.</p> <p>percolation-zd-supercritical-clusters-one-or-infty</p>

The number of infinite clusters is not ∞ for supercritical percolation in \mathbb{Z}^d .

infinite-cluster supercritical-percolation
percolation::zd

percolation-zd-supercritical-clusters-not-infty

Assume $P(N = \infty) = 1$.

- For all k , there exists n such that the probability of k disjoint clusters intersecting $[-n, n]^d$ is strictly positive. Proof: Union over n of these events is $N \geq k$.
- Find a box intersecting three disjoint clusters that are far enough apart. Resample that box.
- The probability of a point being a trifurcation is translation invariant and strictly positive.
- $Cm^d = \mathbb{E}[\# \text{ trifurcations in } [1, m]^d] \leq \# \partial[1, m]^d = O(m^{d-1})$. Contradiction.

Pivotal

pivotal
percolation::zd

percolation-pivotal-def

For an increasing event A , a site z is A -*pivotal* for a configuration v if $v^{z,0} \notin A$ but $v^{z,1} \in A$.

Russo's formula

pivotal
percolation::zd

percolation-russo-formula

If A is an increasing cylindrical event, then

$$\frac{dP_p(A)}{dp} = \mathbb{E}_p[\# \text{ pivots of } A]$$

Proof. Write S the finite set of states that A depends on. Couple percolations by $w_p(x) := 1_{X(x) \leq p}$ where $X(x) \sim \text{Unif}[0, 1]$ are independent. This shows $p \mapsto P_p(A)$ is monotone. Hence, for $\varepsilon > 0$ (treat $\varepsilon < 0$ similarly),

$$\begin{aligned} P_{p+\varepsilon}(A) - P_p(A) &= P(w_{p+\varepsilon} \in A, w_p \notin A) \\ &= \sum_{x \in S} P(X(x) \in [p, p+\varepsilon[, x \text{ pivotal for } w_p) + O(\varepsilon^2) \\ &= \varepsilon \mathbb{E}_p[\# \text{ pivots of } A] \end{aligned}$$

as $X(x) \in [p, p+\varepsilon[$ for several $x \in S$ with probability $O(\varepsilon^2)$. \square

Definitions and setup for exponential decay

infinite-cluster subcritical
percolation::zd

percolation-exponential-decay-setup

- \mathcal{S} the set of finite connected sets in \mathbb{Z}^d containing the origin and whose complement is connected.
- If $S \in \mathcal{S}$, $O(S)$ is the set of neighbors of S and $\tilde{S} = O(S) \cup S$.
- For $S \in \mathcal{S}$, C_S is the connected component of 0 for percolation inside S .
- $u_n(p) = P_p(0 \leftrightarrow \lambda_n)$.
- $\varphi_p(S) = \mathbb{E}[|O(S) \cap O(C_S)|]$ is the expected number of sites of S^c that are neighbors of C_S .

If $\varphi_p(S) < 1$ for some $S \in \mathcal{S}$, $P_p(0 \leftrightarrow \lambda_n)$ decays exponentially.

infinite-cluster subcritical
percolation::zd

percolation-exponential-decay-subcritical

Find n_0 such that $S \subseteq \Lambda_{n_0}$. If $0 \leftrightarrow \lambda_n$, then there is a site $x \in C_S$ adjacent to a site $y \in O(S)$ such that $y \leftrightarrow \lambda_n$ outside of \tilde{C}_S . Therefore, if $0 \in D \subseteq S$,

$$\begin{aligned} &P_p(C_S = D, 0 \leftrightarrow \lambda_n) \\ &\leq \sum_{y \in O(S) \cap O(D)} P_p(C_S = D, y \leftrightarrow \lambda_n \text{ outside of } \tilde{D}) \\ &= P_p(C_S = D) \sum_{y \in O(S) \cap O(D)} P_p(y \leftrightarrow \lambda_n \text{ outside of } \tilde{D}) \\ &\leq P_p(C_S = D) |O(S) \cap O(D)| u_{n-n_0} \end{aligned}$$

Summing over D , we get $u_n \leq \varphi_p(S) u_{n-n_0}$, namely exponential decay.

If $p > p_c$, then $\inf_{S \in \mathcal{S}} \varphi_p(S) > 0$.

infinite-cluster
percolation::zd

percolation-exponential-decay-supercritical

For all $S \in \mathcal{S}$,

$$\varphi_p(S) \geq P_p(0 \leftrightarrow \infty) > 0$$

If $\inf_{S \in \mathcal{S}} \varphi_{p_0}(S) > 0$, then $p_0 \geq p_c$.

infinite-cluster
percolation::zd

percolation-exponential-decay-not-subcritical

Percolate in Λ_n . Call U the set of points connected to λ_n . The expected number of closed $0 \leftrightarrow \lambda_n$ -pivotal is $(1 - p) \frac{du_n(p)}{dp}$ by Russo. A pivotal y is closed iff there is an open path from 0 to a neighbor of y in $S(U)$ (the component of 0 in \tilde{U}^c), and in particular $y \in O(S(U))$. Hence, if $p > p_0$,

$$\begin{aligned} \frac{du_n(p)}{dp} &= \frac{1}{1-p} \sum_{V \not\equiv 0} \mathbb{E}[1_{U=V} \varphi_p(S(V))] \\ &\geq \frac{\alpha}{1-p} P_p(0 \notin U) \geq \alpha \end{aligned}$$

Integrating,

$$P_p(0 \leftrightarrow \infty) \lim_{n \rightarrow \infty} u_n(p) \geq (p - p_0) \alpha > 0$$

The probability of a left-right crossing in a rhombus is $\frac{1}{2}$.

crossing
percolation::triangular

percolation-triangular-top-bottom-left-right

Look at the set of sites connected to the top boundary. Either it reaches the bottom (and we have a top-bottom open crossing) or it doesn't (and the "lower boundary" of the set is a left-right closed crossing). Hence the probabilities of a top-bottom open crossing and of a left-right closed crossing add up to 1. But they are equal by symmetry, hence they must be $\frac{1}{2}$.

<p>For triangular percolation, $p_c \leq \frac{1}{2}$.</p> <div> <div>infinite-cluster critical</div> <div>percolation::triangular</div> <div>percolation-triangular-critical-le-half</div> </div>	<p>At $p = \frac{1}{2}$, the probability of a left-right crossing is $\frac{1}{2}$. In particular, the probability of a point belonging to a cluster of diameter at least N is at least $\frac{1}{2(N+1)}$. Hence we do not have exponential decay and $p_c \leq \frac{1}{2}$.</p>
<p>Glauber dynamic</p> <div> <div>general-models</div> <div>glauber-dynamic-def</div> </div>	<p>Update the configuration one state at a time. Forget a random state and pick between the two possible configurations c and d with probabilities</p> $\frac{P(c)}{P(c) + P(d)}, \frac{P(d)}{P(c) + P(d)}$ <p>The state needn't be chosen with the same probability, but they must each have positive probability of being chosen.</p>
<p>The Glauber dynamic gives rise to a unique stationary measure because...</p> <div> <div>general-models</div> <div>glauber-dynamic-unique-measure</div> </div>	<p>...the Markov chain is</p> <ul style="list-style-type: none"> aperiodic irreducible reversible <p>Indeed it is a random walk on the space of configurations (which is connected and finite).</p>
<p>Harris inequality</p> <div> <div>general-models</div> <div>harris-inequality</div> </div>	<p>If A, B, are two increasing cylindrical events, then $P_\beta(A \cap B) \geq P_\beta(A)P_\beta(B)$</p> <p><i>Proof.</i> Construct two Markov chains X_n and Y_n coupled through a Glauber dynamic such that $X_n \leq Y_n$ and Y_n is constrained to B (possible because B increasing and cylindrical). So $X_n \in A \implies Y_n \in A$ (A is increasing). This proves $P_\beta(A \mid B) \geq P_\beta(A)$. \square</p>

<div>Triangular percolation has no infinite cluster at $p = \frac{1}{2}$.</div> <div> <div>Tags</div> <div>percolation::triangular</div> </div> <div> <div>Label</div> </div>	<div> <p>Assume there is an infinite cluster with probability 1. Consider the $(2N + 1) \times (2N + 1)$ rhombus R_N centered at the origin and its sides L_1, E_2, L_3, L_4. Define E_i the event that $L_i \leftrightarrow \infty$. By Harris, these events are positively correlated, so</p> $P(E_1^c)^4 = \prod_i P(E_i^c) \leq P(E_1^c, \dots, E_4^c) \leq P(R_N \not\leftrightarrow \infty) \rightarrow 0$ <p>Hence $P(E_i) \rightarrow 1$ for each i and the following happens with strictly positive probability: There are infinite open paths from L_1 and L_3 and infinite closed paths from L_2 and L_4. But in that case it is impossible to have a single infinite cluster. Contradiction.</p> </div>
<div>Ising distribution</div> <div> <div>definition</div> <div>ising-model</div> </div> <div> <div>ising-distrib-def</div> </div>	<div> $P_\beta(\sigma) = \frac{1}{Z_\beta} \exp \left(-\beta \sum_{x \sim y} 1_{\sigma_x \neq \sigma_y} \right)$ $= \frac{1}{Z'_\beta} \exp \left(-\frac{\beta}{2} \sum_{x \sim y} \sigma_x \sigma_y \right)$ </div>
<div>How to extend the Ising measure to an infinite graph?</div> <div> <div>ising-model</div> </div> <div> <div>extend-ising-infinite</div> </div>	<div> <p>Consider a cobounded sequence of sets of states S_n, define P_n^+ the Ising model conditioned on the spins being +1 outside S_n. For every increasing cylindrical event A, $P_n^+(A)$ decreases, so it has a limit $P^+(A)$. This defines P^+ for increasing cylindrical events. Now extend by Carathéodory. Define P^- similarly.</p> </div>
<div>How to couple the σ_n^+ together?</div> <div> <div>ising-model</div> </div> <div> <div>ising-coupling-sigma-n</div> </div>	<div> <p>Pick a measure μ on \mathbb{Z}^d such that $\mu\{x\} > 0$ for all x. Create a Markov chain on $\{(\sigma_0^+, \sigma_1^+, \dots) \mid \sigma_0^+ \leq \sigma_1^+ \leq \dots\}$, by starting at 1 everywhere and each time resampling x with probability $\mu\{x\}$. Each truncated Markov chain $(\sigma_0^+, \dots, \sigma_n^+)$ is irreducible, aperiodic, reversible and has a finite state space, so converges to a unique stable measure. Piece these measures together by Kolmogorov extension.</p> </div>
